

## Solubility Equilibria Problems Key

General approach to solving solubility problems:

- I. Write salt dissolution reaction (use Equilibrium arrow!)
  - ⇒ break solid salt (reactant) into ions (product); include charges and coefficients for # of ions!
  - ⇒ don't include water as a reactant!
- II. Write  $K_{sp}$  expression
  - ⇒ don't include solid salt in equilibrium constant!
- III. Set up ICE.
  - ⇒  $x$  = molar solubility
  - ⇒ Can use Molar mass to convert from molar solubility to gram solubility.

- 1) If a saturated solution prepared by dissolving  $\text{CaF}_2$  in water has  $[\text{Ca}^{2+}] = 3.3 \times 10^{-4} \text{ M}$ , what is the value of  $K_{sp}$ ?

Dissolution eq:  $\text{CaF}_{2(s)} \rightleftharpoons \text{Ca}^{2+}_{(aq)} + 2\text{F}^{-}_{(aq)}$     **breaks into 2 F<sup>-</sup> ions not F<sub>2</sub>!**

	$\text{CaF}_{2(s)} \rightleftharpoons \text{Ca}^{2+}_{(aq)} + 2\text{F}^{-}_{(aq)}$		
I		0	0
C		+x	+2x
E		x	2x

Initial [ ]'s = 0

[F<sup>-</sup>] is double the [Ca<sup>2+</sup>]

$x = [\text{Ca}^{2+}] = 3.3 \times 10^{-4} \text{ M}$

$$K_{sp} = [\text{Ca}^{2+}][\text{F}^{-}]^2 \quad [\text{F}^{-}] = 2x = 6.6 \times 10^{-4} \text{ M}$$

$$K_{sp} = (3.3 \times 10^{-4} \text{ M})(6.6 \times 10^{-4})^2 \quad \mathbf{K_{sp} = 1.4 \times 10^{-10}}$$

$$\text{Or } K_{sp} = x(2x)^2 = 4x^3; \text{ plug in } x = 3.3 \times 10^{-4} \text{ M} \quad K_{sp} = 4(3.3 \times 10^{-4})^3 = 1.4 \times 10^{-10}$$

- 2)  $K_{sp}$  for  $\text{Al}(\text{OH})_3$  is  $1.9 \times 10^{-33}$ . Calculate the molar solubility.

Dissolution eq:  $\text{Al}(\text{OH})_{3(s)} \rightleftharpoons \text{Al}^{3+}_{(aq)} + 3\text{OH}^{-}_{(aq)}$

	$\text{Al}(\text{OH})_{3(s)} \rightleftharpoons \text{Al}^{3+}_{(aq)} + 3\text{OH}^{-}_{(aq)}$		
I		0	0
C		+x	+3x
E		x	3x

$$K_{sp} = [\text{Al}^{3+}][\text{OH}^{-}]^3$$

$$1.9 \times 10^{-33} = x(3x)^3$$

$$1.9 \times 10^{-33} = 27x^4$$

$$x = \left( \frac{1.9 \times 10^{-33}}{27} \right)^{1/4} = (7.04 \times 10^{-35})^{1/4} = 2.9 \times 10^{-9} \text{ M}$$

**solubility =  $2.9 \times 10^{-9} \text{ M}$**

- 3) The solubility of  $\text{Ca}(\text{OH})_2$  is found to be 0.233 g/L. Calculate  $K_{sp}$ .

Dissolution eq:  $\text{Ca}(\text{OH})_{2(s)} \rightleftharpoons \text{Ca}^{2+}_{(aq)} + 2\text{OH}^{-}_{(aq)}$

	$\text{Ca}(\text{OH})_{2(s)} \rightleftharpoons \text{Ca}^{2+}_{(aq)} + 2\text{OH}^{-}_{(aq)}$		
I		0	0
C		+x	+2x
E		x	2x

$$K_{sp} = [\text{Ca}^{2+}][\text{OH}^{-}]^2$$

$$K_{sp} = x(2x)^2 = 4x^3$$

**Need mol/L of  $\text{Ca}(\text{OH})_2$**

$$x = \frac{0.233 \text{ g}}{\text{L}} \times \frac{1 \text{ mol}}{74.10 \text{ g}} = 3.14 \times 10^{-3} \text{ M}$$

$$K_{sp} = 4(3.14 \times 10^{-3})^3 = \mathbf{1.24 \times 10^{-7}}$$

4) a) Calculate the molar solubility of  $\text{SrF}_2$  in pure water ( $K_{\text{sp}} = 4.3 \times 10^{-9}$ ).

Dissolution eq:  $\text{SrF}_2(s) \rightleftharpoons \text{Sr}^{2+}(aq) + 2\text{F}^-(aq)$  **breaks into 2 F<sup>-</sup> ions not F<sub>2</sub>!**

	$\text{SrF}_2(s)$	$\rightleftharpoons$	$\text{Sr}^{2+}(aq)$	$+ 2\text{F}^-(aq)$
I			0	0
C			+x	+2x
E			x	2x

$$K_{\text{sp}} = [\text{Sr}^{2+}][\text{F}^-]^2$$

$$4.3 \times 10^{-9} = x(2x)^2 = 4x^3$$

$$x = (4.3 \times 10^{-9}/4)^{1/3} = (1.075 \times 10^{-9})^{1/3}$$

$$x = 1.0 \times 10^{-3} \text{ M} = \text{molar solubility of SrF}_2$$

b) Calculate the molar solubility of  $\text{SrF}_2$  in 0.010 M NaF.

Assume  $\text{SrF}_2$  is added to a NaF solution so  $[\text{Sr}^{2+}]$  is initially 0, but NaF provides  $[\text{F}^-]$ .

NaF is soluble salt:  $\text{NaF} \rightarrow \text{Na}^+ + \text{F}^-$  **F<sup>-</sup> is common ion**

1:1 ratio so  $[\text{NaF}] = [\text{F}^-] = 0.010 \text{ M}$

	$\text{SrF}_2(s)$	$\rightleftharpoons$	$\text{Sr}^{2+}(aq)$	$+ 2\text{F}^-(aq)$
I			0	0.010
C			+x	+2x
E			x	0.010 + 2x

**F<sup>-</sup> comes from NaF, so don't double [F<sup>-</sup>]**

$$K_{\text{sp}} = [\text{Sr}^{2+}][\text{F}^-]^2$$

$$4.3 \times 10^{-9} = x(0.010 + 2x)^2$$

Assume 2x is a lot smaller than 0.010  $\Rightarrow 4.3 \times 10^{-9} = x(0.010)^2$

$$x = \frac{4.3 \times 10^{-9}}{(0.010)^2}$$

$$x = 4.3 \times 10^{-5} \text{ M} = \text{molar solubility of SrF}_2 \text{ with common ion}$$

$\Rightarrow$  **Adding common ion  $\downarrow$  solubility of  $\text{SrF}_2$**

5) **Will a precipitate form** when 0.150 L of 0.10 M lead (II) nitrate and 0.100 L of 0.20 M sodium chloride are mixed? For  $\text{PbCl}_2$ ,  $K_{\text{sp}} = 1.2 \times 10^{-5}$

**DR precipitation reaction:**  $\text{Pb}(\text{NO}_3)_2(aq) + 2\text{NaCl}(aq) \rightarrow \text{PbCl}_2(s) + 2\text{NaNO}_3(aq)$

**Solubility reaction:**  $\text{PbCl}_2(s) \rightleftharpoons \text{Pb}^{2+} + 2\text{Cl}^-$

**Will a precipitate form – indicates we need to find Q for  $\text{PbCl}_2$ !**

$$Q = [\text{Pb}^{2+}][\text{Cl}^-]^2$$

1:1 mole ratios so initial  $[\text{Pb}^{2+}] = [\text{Pb}(\text{NO}_3)_2] = 0.10 \text{ M}$ ; initial  $[\text{Cl}^-] = [\text{NaCl}] = 0.20 \text{ M}$

$$\text{After combining solutions: } [\text{Pb}^{2+}] = \left( \frac{0.10 \text{ M Pb}^{2+} \times 0.150 \text{ L}}{0.250 \text{ L}} \right) = 0.060 \text{ M Pb}^{2+}$$

$$[\text{Cl}^-] = \left( \frac{0.20 \text{ M Cl}^- \times 0.100 \text{ L}}{0.250 \text{ L}} \right) = 0.080 \text{ M Cl}^-$$

$$Q = (0.060)(0.080)^2 = 3.8 \times 10^{-4}$$

**Q > K<sub>sp</sub>, so  $\text{PbCl}_2$  does precipitate. Eq shifts  $\leftarrow$**
