## Equilibrium Key

1. Answer the following three questions for the reaction of HF gas decomposing into hydrogen gas and fluorine gas at $78.5^{\circ} \mathrm{C}$.
a. Write out the balanced reaction and the $K_{c}$ and $K_{p}$ expressions.

$$
\begin{array}{ll}
2 \mathbf{H F}(\mathbf{g}) \leftrightarrows \mathbf{H}_{2}(\mathbf{g})+\mathbf{F}_{2}(\mathbf{g}) & \\
\mathbf{K c}=\frac{\left[\mathrm{H}_{2}\right]\left[\mathrm{F}_{2}\right]}{[\mathrm{HF}]^{2}} & \mathbf{K p}=\frac{\mathrm{P}_{\mathrm{H} 2} \mathrm{P}_{\mathrm{F} 2}}{\mathrm{P}_{\mathrm{HF}}^{2}}
\end{array}
$$

b. Given $K_{p}=4.25 \times 10^{-4}$ calculate $K_{c}$.
$\left(4.25 \times 10^{-4}\right)=K c[(0.08206)(351.5 K)]^{0}$ so $4.25 \times 10^{-4}=K c($ anything raised to 0 is equal to 1$)$
c. If I begin the reaction with 0.224 g of pure hydrogen fluoride in a 1550 mL closed flask, calculate all the equilibrium concentrations for each species in the reaction in units of moles/L.

$$
0.224 \mathrm{~g} \mathrm{HF}\left(\frac{1 \mathrm{~mol}}{20.0 \mathrm{~g}}\right)\left(\frac{1}{1.550 \mathrm{~L}}\right)=7.2258 \times 10^{-3} \mathrm{M}
$$

Set up ICE table

|  | $2 \mathrm{HF}(\mathrm{g})$ | $\leftrightarrows$ | $\mathrm{H}_{2}(\mathrm{~g})$ |
| :--- | :---: | :---: | :---: |
| I | $+\mathrm{F}_{2}(\mathrm{~g})$ |  |  |
| I | .0072258 | 0 | 0 |
| C | -2 x | +x | +x |
| E | $.0072258-2 \mathrm{x}$ | x | x |

Thus $4.25 \times 10^{-4}=x^{2} /(0.0072258-2 x)^{2}$
take the square root of both sides, no quadratic necessary

$$
\begin{aligned}
& 0.020616=x /(0.0072258-2 x) \\
& \text { collect terms } \\
& 1.4896 \times 10^{-4}-0.041232 x=1 x \\
& 1.4896 \times 10^{-4}=1.041232 \mathrm{x} \\
& \mathrm{x}=\left[\mathrm{H}_{2}\right]=\left[\mathrm{F}_{2}\right]=1.43 \times 10^{-4} \mathrm{M} \text { and }[\mathrm{HF}]=6.94 \times 10^{-3} \mathrm{M}
\end{aligned}
$$

2. A 0.0240 mol sample of $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ is allowed to reach equilibrium with $\mathrm{NO}_{2}(\mathrm{~g})$ in a 0.372 L flask at $25.0^{\circ} \mathrm{C}$. Calculate the concentration of $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ at equilibrium. $\quad \mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g}) \leftrightarrows 2 \mathrm{NO}_{2}(\mathrm{~g}) \quad \mathrm{K}_{\mathrm{c}}=4.61 \times 10^{-3}$ initial molarity $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})=\left(\frac{.0240 \mathrm{~mol}}{.372 \mathrm{~L}}\right)=.06452 \mathrm{M}$

|  | $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ | $\leftrightarrows$ |
| :--- | :---: | :---: |
| I | $\mathbf{2} \mathrm{NO}_{2}(\mathrm{~g})$ |  |
| C | .06452 | 0 |
| E | -x | +2 x |
|  | $(.06452-\mathrm{x})$ | 2 x |

$$
\begin{aligned}
& 4.61 \times 10^{-3}=(2 \times)^{2} /(0.06452-x) \\
& 4 x^{2}=-4.61 \times 10^{-3} \times+2.974 \times 10^{-4} \\
& 4 x^{2}+4.61 \times 10^{-3} \times-2.974 \times 10^{-4}=0
\end{aligned}
$$

quadratic formula with $a=4, b=+4.61 \times 10^{-3}$ and $c=-2.974 \times 10^{-4}$ $x=8.065 \times 10^{-3}$ (the other solution is negative and can't have negative concentration) thus $\left[\mathrm{N}_{2} \mathrm{O}_{4}\right]=0.0565 \mathrm{M}$
3. Consider the reaction $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g}) \leftrightarrows 2 \mathrm{NO}_{2}(\mathrm{~g})$, where $\mathrm{K}_{\mathrm{c}}=5.7$ at $250^{\circ} \mathrm{C}$. If the initial concentration of $\mathrm{N}_{2} \mathrm{O}_{4}$ is 0.350 M and that of $\mathrm{NO}_{2}$ is 1.20 M in a flask at $250^{\circ} \mathrm{C}$, will the reaction go forwards or backwards to reach equilibrium? (Must show work for credit)

$$
\mathbf{Q}=\left(\frac{(1.20)^{2}}{0.350}\right)=4.11 \text { which is less than } K \text { so reaction is going forwards till } \leftrightarrows \text { reached }
$$

4. A quantity of 2.40 moles of pure $\mathrm{SO}_{2} \mathrm{Cl}_{2}$ gas was placed in an 8.00 L sealed flask. At 500 K , after equilibrium is established, there are 1.60 moles of the product gas $\mathrm{SO}_{2}$ present. Calculate $\mathrm{K}_{\mathrm{c}}$ for the reaction. $\quad \mathrm{SO}_{2} \mathrm{Cl}_{2}(\mathrm{~g}) \leftrightarrows \mathrm{SO}_{2}(\mathrm{~g})+\mathrm{Cl}_{2}(\mathrm{~g})$
$2.40 \mathrm{~mol} / 8.00 \mathrm{~L}=.300 \mathrm{M}$ initial $\mathrm{SO}_{2} \mathrm{Cl}_{2}(\mathrm{~g})$
$1.60 \mathrm{~mol} / 8.00 \mathrm{~L}=.200 \mathrm{M} \mathrm{SO}_{2}(\mathrm{~g})$ at $\leftrightarrows$

|  | $\mathrm{SO}_{2} \mathrm{Cl}_{2}(\mathrm{~g}) \leftrightarrows$ | $\mathrm{SO}_{2}(\mathrm{~g})$ | $+\mathrm{Cl}_{2}(\mathrm{~g})$ |
| :--- | :--- | :---: | :---: |
| I | .300 | 0 | 0 |
| C | -x |  | +x |
| E | +x |  |  |
| E | $(.300-\mathrm{x})$ |  | .200 |
|  |  |  |  |

So x must $=.200$ so $\mathrm{K}_{\mathrm{c}}=(.200)^{2} / .100=.400$
5. Consider this endothermic reaction: $\mathrm{CO}_{2}(\mathrm{~g})+\mathrm{C}(\mathrm{s}) \leftrightarrows 2 \mathrm{CO}(\mathrm{g})$. To make the most CO gas:
a. You could increase the pressure. (true or false?) _ false
b. You could increase the volume. (true or false?) _ true, more space for more moles of gas
c. You could add more carbon monoxide gas. ( true or false?) $\qquad$ false $\qquad$
d. You could decrease the temperature. (true or false?) $\qquad$ false (heat is a reactant)_
e. You could add more carbon. ( true or false?) $\qquad$ false solids don't affect K_
f. You could add a catalyst. ( true or false?) false, catalysts make rxns reach $\leftrightarrows$ faster $_{-}$
6. Write the equilibrium constant expressions $K_{c}$ and $K_{p}$ and the balanced reaction for the reaction between aqueous potassium sulfate and aqueous calcium nitrate.

$$
\begin{aligned}
& \mathrm{K}_{2} \mathrm{SO}_{4}(\mathrm{aq})+\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq}) \leftrightarrows \mathrm{CaSO}_{4}(\mathrm{~s})+2 \mathrm{KNO}_{3}(\mathrm{aq}) \\
& \mathrm{K}_{\mathrm{c}}=\left[\mathrm{KNO}_{3}\right]^{2} /\left[\mathrm{K}_{2} \mathrm{SO}_{4}\right]\left[\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}\right] \quad \mathrm{K}_{\mathrm{p}}=\text { none, there are no gases }
\end{aligned}
$$

7. Calculate $\mathrm{K}_{\mathrm{p}}$ for the formation of steam reaction if at equilibrium at $150^{\circ} \mathrm{C}$ the gas pressures are 0.145 atm for hydrogen, 0.108 atm for oxygen, and 15.4 atm for steam.

$$
\begin{aligned}
& 2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \leftrightarrows 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \\
& \mathrm{K}_{\mathrm{p}}=\left[\mathrm{H}_{2} \mathrm{O}\right]^{2} /\left[\mathrm{H}_{2}\right]^{2}\left[\mathrm{O}_{2}\right]=(15.4)^{2} /(.145)^{2}(.108)=1.04 \times 10^{5} \text { (product favored) }
\end{aligned}
$$
